FOREWORD

This report is the result of a cooperative effort between the Office of Air Quality Planning and Standards' Air Quality Management Division (AQMD) and the Office of Research and Development's Air and Energy Engineering Research Laboratory (AEERL). The overall management of the program was the responsibility of AQMD. AEERL was responsible for the development of selected VOC species profiles as well as program review.

ABSTRACT

The U S. Environmental Protection Agency (EPA) has several ongoing activities that require speciated volatile organic compound (VOC) or particulate matter (PM) profiles from several source categories In 1980, EPA published the "Volatile Organic Compound (VOC) Species Data Manual, Second Edition" (EPA-450/4-80-015) which provided VOC species profiles for some emission source categories. More recently, EPA published the "Receptor Model Source Composition Library" (EPA-450/4-85-002) which contains particulate matter (PM) species profiles for several source categories As part of an effort to update the VOC and PM profile data bases, EPA has initiated several studies. The objective of the current study was to evaluate, revise, and update (1) the 1980 VOC Data Manual, and (2) the Source Composition Library.

The updated VOC species profile data base is contained in Volume I of this document The VOC profile data base includes VOC profiles from primarily three sources (1) the 1980 VOC Data Manual, (2) new VOC profiles developed from readily available existing data, and (3) new VOC profiles developed from original data as a result of the VOC speciation field sampling program. In addition to the VOC profiles, Volume I contains profile assignments that link a profile to a source category For categories where profile data are not available, the profile assignments are based on engineering judgement.

The revised PM species profile data base is contained in Volume II of this document. The PM profiles were extracted from the Source Composition Library with minor changes in format to facilitate inclusion of additional information in the profiles A limited number of new PM profiles developed from literature review are also included in the PM data base. As in the VOC profile data base, the PM data base also contains profile assignments

EXECUTIVE SUMMARY

The U. S. Environmental Protection Agency (EPA) has several ongoing activities that require speciated volatile organic compound (VOC) or particulate matter (PM) profiles from several source categories. Some of these activities include preparation of air toxics and acid precipitation emission inventories, receptor modeling, and ozone strategy development. In an effort to update the available speciated VOC and PM profile data bases, EPA has initiated studies to (1) revise the "Volatile Organic Compound (VOC) Species Data Manual - Second Edition" (EPA-450/4-80-015); and (2) update the "Receptor Model Source Composition Library" (EPA-450/4-85-002). The revised PM species profile data base is contained in Volume II of this document. This document (Volume I) contains the updated VOC species profile data base.

The objective of the current study was to (1) evaluate, revise, and update the 1980 VOC Data Manual; (2) incorporate the new VOC profiles developed in this study from readily available existing data into the updated VOC species profile data base; and (3) incorporate the new VOC profiles developed as a result of the VOC speciation field program in the updated VOC species profile data base.

Overall, there are over 250 original VOC profiles in this document. Of these profiles, about 30 percent are extracted from the 1980 VOC Data Manual, about 65 percent are new profiles developed from existing data or based on engineering judgement, and about 5 percent are new profiles from the VOC species field program. In addition, this document contains about 50 industry-specific average profiles. The profiles from the 1980 VOC Data Manual cover the following source categories: petroleum products, surface coating operations, external and internal combustion, solid waste disposal, primary and secondary metal production, and asphalt production. Most of the new profiles developed from existing data represent the following source categories: organic chemical manufacturing, storage of organic chemicals, aircraft emissions, oil and gas production, surface coating operations,

mobile sources, and gasoline evaporation. The profiles for the last three categories were replacements for poor quality and/or outdated profiles in the 1980 VOC Data Manual.

The VOC profile data contained in this volume are presented in a format that is basically the same as the one used in the 1980 Data Manual. Each profile contains the following information:

- Profile name
- Profile number
- Profile data quality
- Control device identification
- References
- Data source
- Source Classification Code (SCC)
- Chemical species identified by: Storage and Retrieval of Aerometric Data (SAROAD) code, Chemical Abstract System (CAS) number, species name, molecular weight, weight percent
- Date

In addition to the VOC profiles, this document contains VOC profile assignments for all SCC's in the National Emissions Data System (NEDS) and applicable NEDS area source codes and additional area source codes used in the National Acid Precipitation Assessment Program (NAPAP). Ideally, a profile would be needed to represent each one of these categories. However, the number of categories to be characterized is much larger than the available profiles. Therefore, profile assignments that involve linking a VOC profile to a source category that does not have an original profile assignment are developed using engineering judgement.

Source category profile assignments are especially important in activities such as preparation of air toxics and acid precipitation emission inventories and acid precipitation modeling studies. For several SCC's, profile assignments using engineering judgement were not possible; however, in such cases, industry-specific average profiles were developed. These profiles were developed from original profiles representing other SCC's

within the same industry group. The industry-specific average profiles are intended for use only if there is no other information available. In addition, a "zero" profile which is an overall average based on all the VOC profiles in the data base was developed. This profile is intended for use only as a default profile to represent those SCC's characterized by "zero" or "negligible" VOC emission factors according to the document "Criteria Pollutant Emission Factors for the 1985 Emissions Inventory" (EPA-600/7-87-015) and for which the States or any other agency have reported nonzero emissions.

SECTION 1
INTRODUCTION

The U. S. Environmental Protection Agency (EPA) has several ongoing activities that require speciated volatile organic compound (VOC) profiles from several source categories. Some of these activities are preparation of acid precipitation and air toxics emission inventories and ozone strategy development.

As part of an effort to update the available speciated VOC and PM profile data bases, EPA has initiated studies to (1) revise the "Volatile Organic Compound (VOC) Species Data Manual - Second Edition" (EPA-450/4-80-015); and (2) update the "Receptor Model Source Composition Library" (EPA-450/4-85-002). In the PM area, the updated PM species profile data base containing the profiles from the Source Composition Library and the new PM profiles developed from existing data are compiled in Volume II of this document. Initial efforts in the VOC area have resulted in new profiles developed from literature review. Another study in the VOC area consisted of a field sampling program where new profiles were developed based on original data for selected source categories. The VOC profiles compiled in Volume I of this document are primarily based on (1) 1980 VOC Data Manual, (2) interim document, and (3) field sampling program.

Revision of the 1980 VOC Data Manual consisted of identifying poor quality and/or outdated profiles and replacing them with new VOC profiles. Profiles for which there were no replacements were retained in the data base even if the profiles were of low data quality. In cases where there were several profiles representing a given source category, the most general profile with the highest quality level was selected. The profiles extracted from the 1980 VOC Data Manual were included in the current work without any changes except revisions made to data quality indicators for pure solvent/product profiles. The original references used in developing these profiles in the 1980 VOC Data Manual were also included as part of the references listed in this report. The profiles from the 1980 VOC Data Manual are identified by profile numbers ranging from 0001 through 0333.

The new VOC profiles were developed as a result of literature search efforts that focused on revising the poor quality and/or outdated VOC profiles in the 1980 VOC Data Manual, and filling the existing data gaps primarily in the air toxics area. The key sources of information used included a study conducted for the California Air Resources Board (Reference 1), source assessment and background information documents, Section 114 responses and trip reports from several standard development activities, and work conducted by the Atmospheric Sciences Research Laboratory. In addition, work performed during the Northeast Corridor Regional Modeling Project (NECRMP), work currently in progress under the National Acid Precipitation Assessment Program (NAPAP), data obtained from Environment Canada, and data obtained from States were reviewed (see Appendix A for details of the data gathering and review activities).

Overall, close to 200 new profiles were developed. About 80 percent of the new profiles cover source categories that were not characterized in the 1980 VOC Data Manual, e.g., organic chemical manufacturing, oil and gas production, organic chemical storage, plastics production, textiles, aircraft emissions, etc. The remaining 20 percent are replacements for poor quality and/or outdated profiles in the 1980 VOC Data Manual. Most of these profiles cover the surface coating operations, mobile sources, and gasoline evaporation. Other profiles developed in this study included pure component profiles to represent storage or solvent usage operations that involve handling and use of pure compounds. Development of these profiles was based on engineering judgement.

In several cases, speciated data were available from a single emission source. In cases where data were available from a number of emission sources, the data were composited in proportion to the emissions rate of each source (refer to Appendix A where a detailed description of species profile development is included).

In addition to the profiles developed from existing data, five new VOC profiles were developed from original data that resulted from the VOC speciation test program (see Appendix G for details). These profiles represent the following source categories: gasoline marketed, degreasing, drycleaning, autobody repair, and graphic arts-printing.

The activities where VOC species profiles are applied typically employ SCC codes for point sources and the NEDS area source codes to represent emission source categories. Ideally, each source category would be characterized by an appropriate VOC profile. Since there are much fewer species profiles than source categories, a VOC profile is assigned to other source categories that are judged to be similar to the source category(ies) having the original profile. This document contains VOC profile assignments for all the SCC's in the NEDS data base and the applicable NEDS area source codes. In addition, profile assignments are provided for area source codes used in the NAPAP studies. The development of VOC profile assignments is discussed in detail in Appendix C. Also included in this appendix are the listings of the assignments for both point and area sources.

To provide the reader/user with guidance on the overall quality of data contained in each profile, an arbitrary scheme (A, B, C, D, E) similar to the one used in AP-42 was used to rank each profile. For example, Profile Data Quality A was assigned to profiles that were considered representative of the total population of sources within a given SCC and that were based on sound analytical techniques with full documentation. Profiles based on engineering judgement and that may not be considered representative of the total population were assigned Profile Data Quality E. A more detailed discussion on profile data quality is contained in Section 2.

Data quality indicators were also used to characterize the VOC profile assignments. Where the VOC profile assignment is based on an original profile, the data quality indicator reflects the Profile Data Quality on the profile (see Section 3). In cases where the assignment is based on engineering judgement, the data quality is typically lowered one or more levels depending on how well the profile represents the "new" category.

For several SCC's, profile assignment using engineering judgement was not possible. In such cases, industry-specific average profiles were developed from original profiles representing other SCC's within the same industry group. These profiles have numbers starting with 9 and are recommended for use only if there is no other information available. In addition, Profile 0000 which is an overall average based on all the profiles in the data base was developed. This profile is intended for use only as a

default profile in applications such as emission inventory development. The "zero" profile is applied to those SCC's characterized by "zero" or "negligible" VOC emission factors and for which the States or any other agency have reported nonzero VOC emissions. The SCC's with "zero" and "negligible" emission factors were identified from the document "Criteria Pollutant Emission Factors for the 1985 NAPAP Emissions Inventory" (EPA-600/7-87-015).

This document is divided into four sections with numerous supporting appendices. Section 1 contains this introduction. Section 2 describes the VOC species profile format and discusses the applicability of VOC profiles in various activities. Section 3 contains the VOC profiles for both point sources and area sources, followed by the list of references.

There are seven appendices that provide additional information:

Appendix A - Literature Search and VOC Species Profile Development
Appendix B - Industry-Specific Average Profiles and "Zero" Profile
Appendix C - VOC Profile Assignments
Appendix D - Chemical Species Data File
Appendix E - Chemical Species Classification
Appendix F - Data File Description
Appendix G - VOC Speciation Test Program

SECTION 2
VOC SPECIES PROFILE FORMAT AND APPLICATION

2.1 VOC SPECIES PROFILE FORMAT

Table 2-1 is an example of the format used in presenting the VOC profiles for this document; it is basically the same as that used in the 1980 Data Manual except for a few changes. Although the profiles in the 1980 Data Manual contain chemical classification information for each species, this information is not included in this document, since there are several different classification schemes currently used. However, two examples are included in Appendix E. Another item that is not included in the new VOC profile format is information on volumetric or molar composition (volumetric or molar percentages). Several manual users indicated that this information is of very little use in their work. Each of the entries in Table 2-1 is described below:

Profile name: In a majority of the cases, the profile name is the descriptor used for the applicable source category. In cases where a particular profile is applicable to more than one source category, a more general term is used to identify a given profile.

Profile number: This is a unique number assigned arbitrarily to a profile. A numerical listing of all the VOC profiles in this document is provided in Appendix A.

Profile data quality: A ranking scheme is employed to assign data quality indicators to each profile. This approach is similar to the one used in the 1980 Data Manual and also consistent with the approach used in AP-42 for emission factors. The following criteria were used in assigning data quality indicators:

Data Quality A: Data set based on a composite of several tests using analytical techniques such as GC/MS and can be considered representative of the total population.

SAROAD NUMBER	CAS NUMBER	SPECIES NAME	MOL. WEIGHT	PERCENT WEIGHT
43301	67-75-1	METHYL ALCOHOL	32.04	7.77
43350	115-51-6	DIMETHYLETHER	46.07	66.64
43432	79-92-9	METHYLACETATE	74.08	16.33
43503	75-50-0	ACETALDEHYDE	44.05	8.43
45204	95-54-6	O-XYLENE	106.16	0.83
			SUM TOTAL	100.00

DATE :04-21-1988

Data Quality B:	Data set based on a composite of several tests using analytical techniques such as GC/MS and can be considered representative of a large percentage of the total population. Profiles from the VOC field sampling program are assigned data quality "B."
Data Quality C:	Data set based on a small number of tests using analytical techniques such as GC/MS and can be considered reasonably representative of the total population.
Data Quality D:	Data set based on a single source using analytical techniques such as GC/MS; or data set from a number of sources where data are based on engineering calculations.
Data Quality E:	Data set based on engineering calculations from one source; data set(s) based on engineering judgement; data set(s) with no documentation provided; may not be considered representative of the total population.

Control device: This entry is used to indicate if the profile data represent an emission stream downstream or upstream of a control device (if present) since the composition of the uncontrolled and controlled streams may be significantly different.

Reference(s): This entry identifies the primary reference(s) used in developing the profiles. If more detailed information is required, the user/reader should consult these references.

Data source: This entry briefly describes the basis of the composition data used in the profile (e.g., number of tests, number of sources, analytical methods, how data were composited, etc.). More detailed information about the data used can be obtained from the references indicated.

SCC: This entry is the code for the source category for which the profile was originally developed. These codes are obtained from the current National Emission Data System (NEDS) for point sources (1-01-001-01 through

5-03-900-10) and area sources (01 through 64). Area source codes from 65 through 115 developed under NAPAP are also considered. A listing of area source codes and their descriptions is presented in Table C-3 of Appendix C.

Composition data: Each species in the profile data is identified by a SAROAD code, CAS number, species name, molecular weight, and weight percentage. SAROAD codes were obtained from Volume V of the Aeros Manual Series (third edition, September 1986). For species not contained in this manual, new SAROAD codes have been assigned following the methodology employed in the Aeros Manual.

In some profiles, the weight percentages are followed by peak identifiers (ID's). The peak ID's indicate groups of two or three species identified as a single peak in GC and/or GC/MS analysis. In this document, one of the species in a given peak is arbitrarily assigned the total weight percentage corresponding to the peak. For example, in Profile 1097, peak (1) represents butyraldehyde and crotonaldehyde. The weight percentage for butyraldehyde is indicated as 1.24, while that for crotonaldehyde is listed as 0.00. A footnote is included at the end of such profiles to explain peak ID and its use.

It should also be noted that in some profiles, a given species appears more than once with different weight percentages and as part of different peaks. This is primarily due to the inability to distinguish between isomers of a given species in interpretation of raw GC/MS data. For example, in Profile 1192, the species isomers of undecane appears three times with different weight percentages: (1) zero percent, as part of peak (15) shared with octahydroindene (0.04 percent) and C11 olefins (zero percent); (2) 3.03 percent as a single peak; and (3) zero percent, as part of peak (17) shared with isomers of butylbenzene (0.10 percent).

Most of the CAS numbers were obtained from the National Air Toxics Information Clearinghouse Data Base (1985) and the Registry of Toxic Effects of Chemical Substances (1983 supplement to the 1981-82 edition). For some species/group of species, CAS numbers were not identified.

Date: This entry will be used to indicate the date the profile was last reviewed/updated by EPA.

2.2 LIMITATIONS OF DATA

All data identified through the literature search efforts were used as reported when developing the new profiles in this study. Only those data sets with sufficient documentation were included. No attempt was made to verify the completeness/accuracy of the data. The profile data (i.e., species and weight percentages) extracted from the 1980 VOC Data Manual were incorporated in the updated VOC data base with no changes.

In some cases, the profiles may not be a full characterization of the emission source. Therefore, the user/reader is cautioned to use these profiles with discretion. Nevertheless, the profile data quality indicator provides a qualitative measure of confidence in a particular profile.

Profiles for individual sources may vary considerably from the values provided in this document. Therefore, profiles in this document should not be used to characterize specific sources; rather, they should be used for screening purposes. Source-specific data should always be preferred to the use of literature data presented in this document.

2.3 VOC SPECIES PROFILE APPLICATION

There are several ongoing EPA activities that require speciated VOC data as an input parameter. These activities include preparation of air toxics emission inventories, ozone strategy development, and preparation of acid precipitation inventories. The primary use of the 1980 Data Manual has been in ozone related studies. It is anticipated that the updated VOC profile data base will be applied in preparation of emission inventories as well. This section will briefly discuss how to use this document and provide a specific example to illustrate how to use VOC species profiles in preparation of air toxics emission inventories.

2.3.1 Document Guide

In addition to the VOC profiles contained in Section 3, Appendix C in this document includes VOC profile assignments for all the VOC profiles. This appendix also contains a listing of area source codes and their

descriptions. Appendix A contains a numerical listing of all the profiles and their location in this document.

To identify the applicable profile for a given source category, the reader should (1) refer to Table C-1 or C-2 in Appendix C; (2) identify its location from Table A-1 in Appendix A; and (3) locate the actual profile in Section 3.

2.3.2 Example of Use of Profile

The easiest way to describe how profiles might be applied is to present a hypothetical example: A State air pollution control agency is interested in developing an air toxics emission inventory for the State. An earlier study conducted for the State has identified a list of toxic/potentially toxic compounds from several emission sources. The emission rates of these individual compounds will be used as an input to the proposed air toxics regulatory program for the State.

The profiles can identify the relative amounts of individual compounds in a given emission stream. In most cases, emission factors are available for total VOC's where the compound breakdown is not specified (e.g., AP-42 or the Criteria Pollutant Emission Factor document). The information contained in this document supplements these general emissions data. For a given source category, the appropriate VOC species profile should be identified using Appendix C and the total VOC emission factor should be multiplied by the weight fractions for each compound in the profile to determine compound-specific emission factors.

In this example, formaldehyde is one of the toxic compounds on the State's list and airport operations are a major emission source. From Appendix C, the reader/user identifies the profile appropriate for airport operations. Aircraft emissions are classified as area sources, and Table C-3 lists three types of airport operations (civil, military, commercial). Since the airport in question is commercial, the appropriate profile for area source code 047 is Profile 1098. To locate Profile 1098, the reader should refer to Table A-1 in Appendix A where the location of each profile is given. From this table, Profile 1098 is on page 352. If

the reader/user is concerned with point sources, the SCC and the VOC emission factor for a particular category can be obtained from NEDS or the Criteria Pollutant Emission Factor document.

The weight percentage of formaldehyde in Profile 1098 is 15.00. Applying the weight fraction of formaldehyde to the total VOC emissions for the airport of 500,000 lb/yr, formaldehyde emissions are estimated as 500,000 x 0.15 = 75,000 lb/yr. The reader/user should review the "Data Source" description for the profile to ensure that the data apply to the specific situation on hand. If there are questions, the reader may wish to review the original document on which the profile is based.

SECTION 3
VOC SPECIES PROFILES - POINT AND AREA SOURCES

This section contains all the VOC profiles grouped in 29 separate sections according to source categories. The profiles representing point sources are presented first, followed by those representing area sources. The profiles are ordered numerically within each subsection. The following list can be used to identify and locate the profiles within each section.

3.1 EXTERNAL COMBUSTION BOILERS

External combustion sources include utility, industrial, commercial and institutional boilers; commercial and domestic combustion units; process heaters, furnaces, and kilns. Coal, oil, and natural gas are the major fossil fuels used by these sources.

3.2 INTERNAL COMBUSTION ENGINES

The major types of engines in this category are gas turbines and large, heavy duty, general utility reciprocating engines. Stationary internal combustion engines find applications in electrical power generators, in gas pipeline pump and compressor drives and in various process industries. The majority of gas turbines are used in electrical generation for continuous, peaking or stand-by power. The primary fuels used are natural gas and No. 2 (distillate) fuel oil, although residual oil is used in a few applications.

3.3 CARBON BLACK PRODUCTION

Carbon black is produced by the reaction of a hydrocarbon fuel such as oil or gas with a limited supply of combustion air at temperatures in excess of 2,000^{o}F. The unburned carbon is collected as an extremely fine black fluffy particle, 10 to 500 nm in diameter. The principal uses of carbon black are as a reinforcing agent in rubber compounds (especially tires) and as a black pigment in printing inks, surface coatings, paper and plastics. The major process to manufacture carbon black is the oil furnace process. Emission sources include the main process vent, the dryer vent, the pneumatic transport system vent, the vacuum cleanup system vent, and fugitive sources.

3.4 PAINT MANUFACTURING

Paint manufacture involves the dispersion of a colored oil or pigment, usually in an oil or resin, followed by the addition of an organic solvent for viscosity adjustment. Only the physical processes of weighing, mixing, grinding, tinting, thinning, and packaging take place. No chemical reactions are involved. These processes take place at room temperature in large mixing tanks. The primary factors affecting VOC emissions from paint manufacture are types of solvents used and mixing temperature.

3.6 PLASTICS PRODUCTION

The manufacture of most resins or plastics begins with the polymerization or linking of the basic monomer, usually a gas or liquid, into high molecular weight noncrystalline solids. The manufacture of the basic monomer is not considered part of the plastics industry; it is usually accomplished at a chemical or petroleum plant. The manufacture of most plastics involves an enclosed reaction or polymerization step, a drying step, and a final treating and forming step. Treatment of the resin after polymerization varies with the proposed use. The major VOC emission sources in plastics manufacturing are the emissions of raw materials or monomers, emissions of solvents or other volatile liquids during the reaction, and emissions of solvents during storage and handling of thinned resins.

3.7 PRINTING INK MANUFACTURE

The major types of printing ink are: letterpress, lithographic, flexographic, and rotogravure inks. The ink types vary greatly in composition. The processes involved in printing ink manufacture include: (1) cooking the vehicle and addition of dyes, (2) grinding the pigment into the vehicle, and (3) replacing water in the wet pigment pulp with an ink vehicle. The ink vehicle is cooked to 93-315^{o}C for 8-12 hours. Pigment and vehicle mixing is done with dough mixers or in agitated tanks. Horizontal or vertical mills are used for grinding.

3.8 SYNTHETIC ORGANIC FIBER PRODUCTION

Semi-synthetic fibers result when natural polymeric materials such as cellulose are dissolved or dispersed and then spun into fine filaments. True synthetic fibers result from addition and other polymerization reactions that form long chain molecules. The manufacture of true synthetic fibers begins with the preparation of extremely long, chain-like molecules. The polymer is then spun in one of four ways: melt spinning, dry spinning, wet spinning, or core spinning. Emissions may occur during these processes or during drying of the finished fiber.

PROFILE NAME:Synthetic Organic Fiber Production - Nylon Batch Production Process

PROFILE NUMBER:1092
PROFILE DATA QUALITY:D

CONTROL DEVICE:Not reported

REFERENCE(S):51
DATA SOURCE:The evaporator vessel vent stack was sampled during three separate evaporation cycles with one hexamethylenediamine emissions run performed during each cycle. Total organic carbon as carbon cations were recalculated using a molecular weight ratio for conversion to hexamethylenediamine.

3.9 ORGANIC CHEMICAL MANUFACTURING

The organic chemical industry is a large and diverse industry producing a large number of intermediate and end-product organic chemicals. A large proportion of the emissions from the chemical manufacturing industry occur as organic vapors. Organic particulate emissions may also be generated in some processes. The emissions typically contain raw material (including impurities) used and intermediate and final products formed during the manufacturing process. Emissions sources include storage and handling emissions, reactor process emissions, separation process emissions, fugitive emissions, and secondary emissions (e.g., from waste treatment).

3.10 FOOD AND AGRICULTURE

This category includes farming operations and meat and crop processing. Processes involved in the production of food and agricultural products include harvesting, refinement, preservation, storage and handling, and packaging. Refinement processes can include cleaning, drying, grinding, mixing, and fermentation. Particulate emissions are the dominant emission type from this source category.

3.11 PRIMARY AND SECONDARY METAL PRODUCTION

Primary metal production involves many processes which basically produce metals in elemental form from unprocessed and impure ore. Secondary metal operations involve the cleaning, melting, refining, and pouring of metals recovered from scrap. Each process in primary and secondary metal production is a potential source of emissions.

PROFILE NAME:By Product Coke Oven Stack Gas

PROFILE NUMBER:0011
PROFILE DATA QUALITY:C

CONTROL DEVICE:Uncontrolled

REFERENCE(S):58, 59
DATA SOURCE:Composite profile based on test samples taken from two different coke oven stacks and analyzed by GC/MS.

3.12 ASPHALT PRODUCTS

This category includes manufacture of asphalt roofing felts and shingles that involve saturating fiber media with hot asphalt by means of dipping and/or spraying. Preparation of the asphalt saturant (blowing) consists of oxidizing the asphalt by bubbling air through the liquid asphalt. Potential sources of emissions include spraying and dipping, air blowing, hot asphalt storage, and tar kettles. Hot-mix asphalt paving operations are also included in this category. A typical hot-mix paving plant consists of an oil- or gas-fired rotary dryer, a screening and classifying system, a weighing system for asphalt cement and aggregate, a mixer, and the necessary material handling equipment. Potential sources of emissions include the rotary dryer, asphalt-aggregate mixer, truck loading area, and asphalt oil storage.

3.13 PETROLEUM INDUSTRY

The petroleum industry includes petroleum refining and natural gas processing. Petroleum refining involves the production of several fuels, oils, and feeds for the petrochemical industry from crude oil. Refining processes include distillation, conversion, treatment, and storage and handling processes. The most significant sources of emissions include transfer and handling operations, vacuum distillation, catalytic cracking, thermal cracking, boilers, and heaters. Natural gas processes include condensate removal and "sweetening."

3.14 PLYWOOD PRODUCTION

Plywood is made by adhering layers of thin wood or veneers onto a wood core. Processes involved in plywood production include: (1) sawing wood into veneers, (2) drying, (3) application of adhesive, (4) hot press operation, and (5) finishing. Finishing may include sanding, trimming, or treatment.

3.15 SYNTHETIC RUBBER PRODUCTION

Emulsion type and solution type polymerization reactions are used to produce styrene-butadiene copolymers. The emulsion products can be sold in either a granular solid form, known as crumb, or in a liquid form, known as latex. Copolymers of styrene and butadiene can be made with properties ranging from those of a rubbery material to those of very resilient plastic. Uncontrolled VOC emissions may pass to the atmosphere during the emulsion crumb process and from blending/coagulation tanks and dryers.

3.17 TEXTILE PRODUCTS

The textile manufacturing industry converts natural and man-made fibers into fabrics and other textile products. Fibers are processed into yarns which are woven, knit, or otherwise processed into fabrics. The fabrics are then dyed, printed, and/or finished. Finished fabrics are then converted into apparel or other products such as upholstery, sheeting, and draperies by the apparel industry. Potential emission sources include process unit operations, vented fugitive emissions, and chemical and fuel storage tanks.

PROFILE NAME:Textile Products - General Fabric Operations - Dyeing and Curing

3.18 ORGANIC SOLVENT EVAPORATION

Organic solvent evaporation is a source of emissions with several operations. These operations include but are not limited to: dry cleaning, degreasing, petroleum and chemical storage, surface coating applications, asphalt related processes, solvent use, printing, and graphic arts.

3.19 SURFACE COATING OPERATIONS

Surface coating operations primarily involve the application of paint, varnish/shellac, lacquer, enamel, or paint primer for surface decoration and/or protection before products are marketed. Adhesives, as the name implies, involve the application of a bonding agent for the purpose of adhering materials together. A number of basic industrial coating operations are utilized, including spraying, flowcoating, roller coating, dipping and electro-coating. There are variations and combinations of these operations, each designed for a special task. The coatings applied in these operations vary widely as to composition and physical properties. In order to accelerate the drying of the solvents used in the surface coatings, a drying or baking operation is usually an integral part of the basic coating process.

3.20 STORAGE, TRANSPORTATION, AND MARKETING OF PETROLEUM PRODUCTS

The storage, transportation, and marketing of petroleum liquids involves many distinct operations, each of which represents a potential source of VOC evaporative loss. Petroleum liquids are transported or conveyed by tankers, barges, tank cars, tank trucks, and pipelines. Refined fuels are delivered by tank trucks to service stations, commercial accounts, and local bulk storage plants. Emission sources include working and breathing storage losses, and loading, transit, and refueling losses. Refueling losses include evaporative emissions that occur from vapor displacement during vehicle refueling operations.

*The numbers in the parentheses indicate groups of two or three species identified as a single peak in GC analysis. Only one of the species is assigned the weight percent.

3.21 PRINTING/PUBLISHING PROCESSES

Printing may be performed on coated and uncoated paper as well as other surfaces such as metals and fabric. Printing always involves the application of ink by a printing press. Typical printing processes include application of a relatively high solvent content material to the surface of a moving web or film, rapid solvent evaporation by movement of heated air across the wet surface, and solvent-laden air exhausted from the system.

3.22 ORGANIC CHEMICAL STORAGE

Five basic storage vessel designs are used for organic chemical storage: fixed roof, external floating roof, internal floating roof, variable vapor space, and pressure. Typically, organic liquids in the chemical industry are composed of pure chemicals or mixtures of chemicals with similar true vapor pressures. Sources of emissions from organic chemicals in storage include: fixed roof breathing losses, fixed roof working losses, floating roof standing storage losses, floating roof withdrawal losses, variable vapor space filling losses, and pressure tank losses.

3.23 RAILCAR, TANK TRUCK, AND DRUM CLEANING

Rail tank cars, tank trucks, and drums are used to transport about 700 different commodities. Rail tank cars and most tank trucks and drums are in dedicated service (carrying one commodity only) and, unless contaminated, are cleaned only prior to repair or testing. Cleaning agents include steam, water, detergents, and solvents which are applied using steam hoses, pressure wands, or rotatory spray heads. Vapors from cleaning which are not flared or dissolved in water are emitted to the atmosphere.

3.24 SOLID WASTE DISPOSAL

Solid waste sources can be industrial, urban, agricultural, or construction. Solid waste may be disposed of in landfills or land application units or incinerated. A large percentage of urban and industrial waste is burned. Waste burning processes include open burning and controlled and uncontrolled incineration where significant particulate emissions may be generated.

3.25 WOOD COMBUSTION

Wood is burned in industrial/commercial boilers to obtain heat energy and to alleviate waste disposal problems in the pulp and paper industries. Residential wood burning is commonly used to supplement conventional heating systems. In the industrial sector, the burning of wood waste in boilers is mostly confined to those industries where wood is available as a by-product. A variety of boiler configurations is used for burning wood waste. These include dutch oven configurations, spreader stokers, and tangentially-fired or cyclone-fired boilers. Residential wood stoves are usually radiating or circulatory designs constructed from cast iron, heavy gauge sheet metal, or stainless steel. Emissions from wood combustion are affected by furnace design and operating conditions, and fuel characteristics such as fuel composition, moisture content, and effective burning surface area.

PROFILE NAME:Residential Wood Combustion (C-1 - C-6)

PROFILE NUMBER:1084
PROFILE DATA QUALITY:D

CONTROL DEVICE:Catalyst

REFERENCE(S):15
DATA SOURCE:Five samples were taken into a preevacuated 3-liter glass bulb. Four test runs were with a catalyst in use, one when it was not. Samples were analyzed using a combination of mass spectrometry and trace gas chromatographic techniques. (See also profile 1167).

3.26 MOBILE SOURCES

Because of their widespread use, the internal combustion gasoline powered engine in mobile applications is a major source of VOC emissions. Gasoline fueled light-duty vehicles account for about 75 percent of VOC emissions from mobile sources (1983). Automotive VOC emissions consist of exhaust emissions that occur from the tailpipe, evaporative emissions that occur from (1) the gas tank as the temperature rises during the day, (2) the carburetor after the engine has been shut off (hot soak emissions), and (3) emissions from vehicle refueling. This section also contains data on diesel vehicles. Profile data for refueling are included in Section 3.20.

3.27 AIRCRAFT

Aircraft engines are primarily reciprocating piston and gas turbine. Aircraft emissions of concern typically occur during landing/takeoff (LTO) cycles. Each class of aircraft has its own typical LTO cycle which includes all of the normal flight and ground operation modes. These operations are divided into five modes: approach, taxi/idle in, taxi/idle out, takeoff, and climbout.

PROFILE NAME:Aircraft Landing/Takeoff (LTO) - Military

PROFILE NUMBER:1097
PROFILE DATA QUALITY:B

CONTROL DEVICE:Uncontrolled

REFERENCE(S):53
DATA SOURCE:Composite profile developed from data for a CFM-36 jet engine fired with JP-5 fuel at idle, 30% thrust and 80% thrust. Data collected by GC/MS and DNPH analyses were combined according to average LTO cycle times obtained from AP-42 (4th. Edition) for military aircraft.

3.28 FOREST FIRES

A forest "wildfire" is a large-scale natural combustion process that consumes various types of botanical specimens growing outdoors in a defined geographical area. The size and intensity of a wildfire is dependent on such variables as the local meteorological conditions, tree types and their moisture content, and the weight of consumable fuel per acre (fuel loadings). Forest fire emissions are a complex mixture of solids, liquids, and gases. Carbon dioxide and water vapor constitute over 90 percent of the total mass emitted.

APPENDIX A

LITERATURE SEARCH AND VOC SPECIES PROFILE DEVELOPMENT

APPENDIX A
LITERATURE SEARCH AND VOC SPECIES PROFILE DEVELOPMENT

This appendix briefly summarizes the literature search conducted in this study and describes how new VOC profiles were developed from these data.

A.1 LITERATURE SEARCH AND DATA REVIEW

Before conducting a literature search to collect new data, the 1980 Data Manual was carefully reviewed to identify poor quality and/or outdated profile data, and data gaps. The data confidence levels assigned to each profile in the Data Manual were used as a criterion for poor quality. Profiles for the following source categories were identified to be of poor quality: surface coating, printing press, solvent use, solid waste incineration, petroleum industry, chemical manufacturing, textiles, mineral products, and internal combustion engines. Conversations with users of the Data Manual have helped to identify outdated data (e.g., mobile sources, gasoline storage/marketing/ handling, and organic solvent usage).

The first step in data collection was to conduct a computerized literature search of the Engineering Index, Chemical Abstracts, and National Technical Information Services data bases. The key words (and several combinations) used in the search included the following:

VOC
Volatile organic compound
Speciation
Organic species profiles
Profiles
Emission inventories (air)
Photochemical modeling
Volatile matter
Smog
Exhaust emissions
Gasoline motor vehicle emissions
Diesel motor vehicle emissions
Organic solvents
Hydrocarbon composition

Chemical species distribution
Species
Particulate matter profiles
PM_{10}
PM
Particles
Hydrocarbon emissions
Reactive organic compounds
Reactive hydrocarbons
Cleaning solvents
Household (consumer) products
Asphalt
Petroleum products
Textile industry
Degreasing
Vegetation
Natural emissions
Biogenic

The literature search efforts also focused on the following list of toxic/potentially toxic air pollutants:

Arsenic
Asbestos
Benzene
Beryllium
1,3-Butadiene
Cadmium
Carbon tetrachloride
Chloroform
Chromium
Coke oven emissions
Ethylene dibromide
Ethylene dichloride
Ethylene oxide
Formaldehyde
Gasoline vapors
Mercury
Methylene chloride
Perchloroethylene
Polycyclic organic matter
Radionuclides
Trichloroethylene
Vinyl chloride
Vinylidene chloride

Although no particulate matter (PM) profiles are contained in the interim document, the computerized literature search efforts also included PM species. Information identified relating to PM species will be used in the second phase of this study.

One of the key references used in this study was a study conducted for the California Air Resources Board (Improvement of the Emission Inventory for Reactive Organic Gases and Oxides of Nitrogen in the South Coast Air

Basin, Reference 1). Other sources of information reviewed included the National Acid Precipitation Assessment Program (NAPAP), Northeast Corridor Regional Modeling Project (NECRMP), State data files, Atmospheric Sciences Research Laboratory, Environment Canada, and Section 114 responses and trip reports from several standard development activities. See Section 4.0 References for a complete listing of references used to develop the new profiles. (This list does not include the documents that were also reviewed but not found useful.)

A.2 VOC SPECIES PROFILE DEVELOPMENT

A.2.1 Profile Development Based on Existing Data

All data identified through the literature search efforts were used as reported. No attempt was made to verify their completeness. Only those data for which original documentation was available were included. The data used in developing the profiles were available in different forms. Some of the data were already expressed as weight percentages. In other cases, calculations were necessary to convert from volumetric percentage (or mole percentage) and emission flow rate (volumetric or mass rate) to weight percentages.

For several cases, data available from a number of facilities/sources were combined in proportion to the VOC emissions from each facility/source to develop a composite profile. For example, in developing Profile 1070 (methanol production - purge gas vent), two sets of data each based on volume percent were available. The first calculation consisted of conversion from volume percent to weight percent. Assuming 100 lb. moles of VOC gas mixture, the weight of each species in the mixture was calculated by multiplying its volume percent by its molecular weight. The weight percentages were calculated by dividing the weight of each species by the total weight and multiplying by 100. These calculations are summarized below:

Species	Molecular Weight	Stream A Vol %	Stream A Weight lb	Stream A Weight %	Stream B Vol %	Stream B Weight lb	Stream B Weight %
Methanol	32.04	0.20	6.41	0.39	2.62	83.94	4.18
Dimethyl ether	46.10	1.72	79.29	4.78	12.08	556.89	27.72
Methane	16.04	98.08	1573.20	94.83	85.29	1368.05	68.10
			1658.90			2008.88	

These two streams were combined in proportion to their VOC emissions to develop Profile 1070. The VOC emission rates for Stream A and B were 1059 lb/hr and 462 lb/hr, respectively. The data for Stream A were weighted by a factor of [1059/(1059 + 462)] = 0.6963 and for Stream B were weighted by a factor of [462/(1059 + 462)] = 0.3037 as shown below:

Composite Data:

Species		Weight %
Methanol	(0.39 x 0.6963) + (4.18 x 0.3037) =	1.54
Dimethyl ether	(4.78 x 0.6963) + (27.72 x 0.3037) =	11.75
Methane	(94.83 x 0.6963) + (68.10 x 0.3037) =	86.71

In a few cases, developing composite profiles was based on more complex calculations. For example, in developing Profile 1101 (light duty gasoline vehicles) for calendar year 1987, exhaust and evaporative (hot soak) emission composition data for 46 in-use passenger cars using two different fuels were composited using information from AP-42 (fourth edition). Data from the 46 in-use passenger car study did not contain measurements of diurnal emission composition. Therefore, diurnal emission composition data were estimated using data from two other studies (see References 1 and 2 at the end of this appendix).

The data set from the 46-car study was representative of in-use vehicles from 1975 to 1982. For model years <1975 and >1982, it was assumed that the data for model years 1975 and 1982, respectively, would be

representative. For model years <1975, this is equivalent to assuming the effect of noncatalyst vehicles on the overall profile will be small due to their small travel fraction.

In developing Profile 1101, average exhaust and evaporative emission profiles for each model year were weighted according to the exhaust and evaporative hydrocarbon emission rates reported in AP-42 for light duty gasoline vehicles - low altitude (includes tampering). Then, the composite profile for each calendar year was weighted in proportion to the travel fraction for that model year to yield Profile 1101. The travel fractions were calculated using the information in AP-42. In the profile data, 15 percent of n-butane in exhaust emissions was assumed to exist as 1,3-butadiene (see References 2 and 3 at the end of this appendix).

In addition to Profile 1101, Profiles 1203 and 1204 were developed using the 46-car study to represent exhaust and evaporative emissions, respectively, from light-duty gasoline vehicles. The approach used in developing these profiles was the same as that used for Profile 1101 except for the step where the exhaust and evaporative emissions data were composited.

Table A-1 provides a numerical listing of new profiles contained in this document including the profile name and its location in this volume.

A.2.2 Profile Development Based on Engineering Judgement

Pure Component Profiles - For several categories representing storage of pure organic chemicals or use of pure solvents in operations such as dry cleaning, degreasing, or surface coating, new VOC profiles were developed using engineering judgement. In all cases, these profiles consisted of a single species with a weight percent of 100.

Industry-Specific Average Profiles - In characterizing SCC's with profile assignments, there were several instances where it was difficult to make profile assignments based on engineering judgement. For such SCC's, industry-specific average profiles were developed from original profiles representing other SCC's within the particular industry group. These profiles have profile numbers beginning with 9 and they are assigned a data

quality level of "E." The industry-specific average profiles are recommended for use only if no other information is available. These profiles are presented in Appendix B.

"Zero" Profile - Profile 0000 is an overall average of all the VOC profiles in the data base. It is intended for use as a default profile in emission inventory development applications to characterize nonzero VOC emissions reported for SCC's that are associated with "zero" or "negligible" VOC emission factors. The SCC's with "zero" or "negligible" VOC emission factors are based on the document "Emission Factors for the 1985 NAPAP Emissions Inventory" (EPA-600/7-87-015).

TABLE A-1. PROFILE LISTING

Profile Number	Profile Name	Page Number
0001	External Combustion Boiler - Residual Oil	22
0002	External Combustion Boiler - Distillate Oil	23
0003	External Combustion Boiler - Natural Gas	24
0004	External Combustion Boiler - Refinery Gas	25

APPENDIX B

INDUSTRY-SPECIFIC AVERAGE PROFILES AND "ZERO" PROFILE

APPENDIX B
INDUSTRY-SPECIFIC AVERAGE PROFILES AND "ZERO" PROFILE

This appendix contains the industry-specific average profiles developed from original profiles representing specific SCC's within the particular industry group. These profiles are recommended for use only if no other information is available. Since there is no specific SCC associated with these profiles, the entry for SCC designation on the profile is modified as "no original SCC."

This appendix also contains Profile 0000 which is an overall average of all the VOC profiles in this document. This profile is intended for use as a default profile to characterize nonzero VOC emissions reported by States or any other agency for SCC's with "zero" or "negligible" VOC emission factors in the "Criteria Pollutant Emission Factors for the 1985 NAPAP Emissions Inventory" (EPA-600/7-87-015).

A numerical listing of the profiles included in this appendix is given below:

Profile Number	Profile Name
0000	Overall Average
9001	External Combustion Boilers - Industrial - Average
9002	Internal Combustion - Average
9003	Industrial Processes - Average
9004	Chemical Manufacturing - Average
9005	Plastics Production - Average
9006	Synthetic Organic Fiber Production - Average
9007	Alcohols Production - Average
9008	Food and Agriculture - Average
9009	Primary Metal Production - Average

Profile Number	Profile Name
9010	Secondary Metal Production - Average
9011	Mineral Products - Average
9012	Petroleum Industry - Average
9013	Pulp and Paper Industry - Average
9014	Rubber and Miscellaneous Plastics Products - Average
9015	Oil and Gas Production - Average
9016	Textile Products - Average
9017	Drycleaning/Degreasing - Average
9021	Surface Coating Operations - Average
9022	Solid Waste Disposal - Average
9023	Thinning Solvents - Average
9024	Petroleum Product Storage - Average
9025	Bulk Terminals - Petroleum Storage Tanks - Average
9026	Printing/Publishing - Average
9027	Transportation and Marketing of Petroleum Products - Average
9028	Organic Chemical Storage - Average
9029	Organic Chemical Storage - Fixed Roof Tanks - Alcohols - Average
9030	Organic Chemical Storage - Fixed Roof Tanks - Alkanes - Average
9031	Organic Chemical Storage - Fixed Roof Tanks - Alkenes - Average
9032	Organic Chemical Storage - Fixed Roof Tanks - Amines - Average
9033	Organic Chemical Storage - Fixed Roof Tanks - Aromatics - Average

Profile Number	Profile Name
9034	Organic Chemical Storage - Fixed Roof Tanks - Carboxylic Acids - Average
9035	Organic Chemical Storage - Fixed Roof Tanks - Esters - Average
9036	Organic Chemical Storage - Fixed Roof Tanks - Glycol Ethers - Average
9037	Organic Chemical Storage - Fixed Roof Tanks - Glycols - Average
9038	Organic Chemical Storage - Fixed Roof Tanks - Halogenated Organics - Average
9039	Organic Chemical Storage - Fixed Roof Tanks - Isocyanates - Average
9040	Organic Chemical Storage - Fixed Roof Tanks - Ketones - Average
9041	Organic Chemical Storage - Floating Roof Tanks - Aldehydes - Average
9042	Organic Chemical Storage - Floating Roof Tanks - Alkanes - Average
9043	Organic Chemical Storage - Floating Roof Tanks - Ethers - Average
9044	Organic Chemical Storage - Floating Roof Tanks - Halogenated Organics - Average
9046	Organic Chemical Storage - Pressure Tanks - Alkenes - Average
9047	Organic Solvent Evaporation - Miscellaneous - Average

PROFILE NAME:Over all Average

APPENDIX C

VOC PROFILE ASSIGNMENTS

APPENDIX C
VOC PROFILE ASSIGNMENTS

The activities where VOC species profiles are applied typically employ Source Classification Codes (SCC's) for point sources and area source codes from the National Emissions Data System (NEDS) to represent the emission source categories. Ideally, each source category would be characterized by an appropriate VOC (and/or PM) profile. However, there are a limited number of VOC species profiles that represent a relatively small number of source categories. To increase the usefulness of a given VOC profile and to characterize those source categories for which there are no profiles, VOC profile assignments are made based on engineering judgement.

For several SCC's in the Criteria Pollutant Emission Factor document, the VOC emission factor is designated as "zero" or "negligible." Profile 0000 was assigned to these categories. As described in Appendix B, Profile 0000 is an overall average of all the profiles in the VOC species profile data base. It is intended for use as a default profile in large-scale computer applications of the VOC data base for developing emission inventories. In such applications, the "zero" profile will not be used unless nonzero VOC emissions are reported by the States or any other agency for an SCC which is designated in the Criteria Pollutant Emission Factor document as having a "zero" or "negligible" emission factor. For some SCC's, profile assignments were made although the VOC emission factor was "zero" or "negligible." These SCC's involved profiles with high data quality levels.

There were several cases where it was not possible to make an assignment based on engineering judgement. For these cases, industry-specific average profiles were developed from original profiles representing individual SCC's within the particular industry group.

Table C-1 is the listing of all the point source categories that are characterized by the VOC profiles included in this document. Descriptions of the source categories represented by SCC's can be obtained from "Criteria

Pollutant Emission Factors for the 1985 NAPAP Emissions Inventory" (EPA-600/7-87-015). Table C-2 is the listing for the area source codes. In addition to the area source codes from NEDS, profile assignments are provided for additional area source codes used in the National Acid Precipitation Assessment Program (NAPAP). A listing of area source codes and their descriptions are presented in Table C-3.

The entry "Data Quality" in the two tables is based on the Profile Data Quality description. Where the VOC profile assignment is based on an original profile, this parameter reflects the Profile Data Quality as it appears in Section 3. In cases where the assignment is based on engineering judgement (as indicated by an asterisk [*]), the data quality is lowered one or more levels, depending on how well the profile represents the "new" source category. If an original profile represents a pure compound, then the data quality is kept the same when this profile is used to represent the source categories describing the storage of that compound. For industry-specific average profiles, the data quality level associated with the assignment is "E." These profiles are recommended for use only if there is no other information available.

APPENDIX D

CHEMICAL SPECIES DATA FILE

APPENDIX D

CHEMICAL SPECIES DATA FILE

In this appendix, Table D-1 presents an alphabetical listing of all species used in the profiles including their molecular weight, SAROAD code, and CAS number. Table D-2 presents the same information ordered according to SAROAD codes.

If the CAS number for a species were not readily available, this is indicated by a "0" in the appropriate column. This does not mean that the CAS number for a particular species is zero. For several uncommon species, it was difficult to find or calculate molecular weights. An estimate is provided for these species. In cases where a species represents a group or class of compounds, an average molecular weight value is provided.

APPENDIX E

CHEMICAL SPECIES CLASSIFICATION

APPENDIX E

CHEMICAL SPECIES CLASSIFICATION

This appendix contains two examples of chemical species classification schemes (Tables E-1 and E-2). Since there are several different schemes used based on specific modeling needs, chemical species classification data are not included in the profiles in the text.

TABLE E-1. HYDROCARBON SPECIES/CLASS ASSIGNMENTS FOR 1980 NAPAP INVENTORY VERSION 5.2

HYDROCARBON SPECIES	SPECIES SAROAD CODE	5.2 REACTIVITY CLASS
UNIDENTIFIED HYDROCARBONS	43000	09
ISOMERS OF HEXANE	43105	09
ISOMERS OF HEPTANE	43106	09
ISOMERS OF OCTANE	43107	09
ISOMERS OF NONANE	43108	09
ISOMERS OF DECANE	43109	09
ISOMERS OF UNDECANE	43110	09
ISOMERS OF TRIDECANE	43111	09
ISOMERS OF DODECANE	43112	09
ISOMERS OF TETRADECANE	43113	09
ISOMERS OF PENTADECANE	43114	09
C-7 CYCLOPARAFFINS	43115	09
C-8 CYCLOPARAFFINS	43116	09
C-9 CYCLOPARAFFINS	43117	09
MINERAL SPIRITS	43118	09
LACTOL SPIRITS	43119	09
ISOMERS OF BUTENE	43120	15
ISOMERS OF PENTENE	43121	15
ISOMERS OF PENTANE	43122	09
TERPENES	43123	15
METHANE	43201	01
ETHANE	43202	02
ETHYLENE	43203	10
PROPANE	43204	03
PROPYLENE	43205	11
ACETYLENE	43206	09
CYCLOPROPANE	43207	09
PROPADIENE	43208	15
METHYLACETYLENE	43209	15
N-BUTANE	43212	04
BUTENE	43213	15
ISOBUTANE	43214	05
ISOBUTYLENE	43215	13
1,3-BUTADIENE	43218	15
ETHYLACETYLENE	43219	15
N-PENTANE	43220	07
ISOPENTANE	43221	08
3-METHYL-1-BUTENE	43223	15
1-PENTENE	43224	15
CIS, 2-PENTENE	43227	15
2-METHYL,2-BUTENE	43228	15
N-HEXANE	43231	09
N-HEPTANE	43232	09
N-OCTANE	43233	09
N-NONANE	43235	09

TABLE E-1. (Continued)

HYDROCARBON SPECIES	SPECIES SAROAD CODE	5.2 REACTIVITY CLASS
N-DECANE	43238	09
N-UNDECANE	43241	09
CYCLOPENTANE	43242	09
1-HEXENE	43245	15
2,4, DIMETHYL PENTANE	43247	09
CYCLOHEXANE	43248	09
N-DODECANE	43255	09
N-TRIDECANE	43258	09
N-TETRADECANE	43259	09
N-PENTADECANE	43260	09
METHYLCYCLOHEXANE	43261	09
METHYLCYCLOPENTANE	43262	09
1-HEPTENE	43264	15
1-OCTENE	43265	15
3,3 DIMETHYL, 1-PENTENE	43268	15
N-HEXADECANE	43281	09
N-HEPTADECANE	43282	09
N-OCTADECANE	43283	09
N-NONADECANE	43284	09
N-EICOSANE	43285	09
N-HENEICOSANE	43286	09
N-DOCOSANE	43287	09
C8 OLEFIN UNK	43290	15
METHYL ALCOHOL	43301	09
ETHYL ALCOHOL	43302	09
N-PROPYL ALCOHOL	43303	09
ISOPROPYL ALCOHOL	43304	09
N-BUTYL ALCOHOL	43305	09
ISOBUTYL ALCOHOL	43306	09
BUTYL CELLOSOLVE	43308	09
TERT-BUTYL ALCOHOL	43309	09
METHYL CELLOSOLVE	43310	09
CELLOSOLVE	43311	09
DIACETONE ALCOHOL	43320	26
ETHYL ETHER	43351	09
GLYCOL ETHER	43367	09
GLYCOL	43368	09
PROPYLENE GLYCOL	43369	09
ETHYLENE GLYCOL	43370	09
TETRAHYDROFURAN	43390	09
ACETIC ACID	43404	28
METHYL ACETATE	43432	29
ETHYL ACETATE	43433	29
PROPYL ACETATE	43434	29
N-BUTYL ACETATE	43435	29

TABLE E-1. (Continued)

HYDROCARBON SPECIES	SPECIES SAROAD CODE	5.2 REACTIVITY CLASS
ETHYL ACRYLATE	43436	15
CELLOSOLVE ACETATE	43443	09
ISOPROPYL ACETATE	43444	09
METHYL AMYL ACETATE	43445	09
ISOBUTYL ACETATE	43446	09
DIMETHYLFORMAMIDE	43450	24
ISOBUTYL ISOBUTYRATE	43451	09
2-ETHOXYETHYL ACETATE	43452	09
FORMALDEHYDE	43502	21
ACETALDEHYDE	43503	22

APPENDIX F

DATA FILE DESCRIPTION

APPENDIX F

DATA FILE DESCRIPTION

The VOC Speciation Data Base consists of five separate files. The content of each file is as follows:

	File	Contents
1.	GENERAL	Profile number Profile name Profile data quality Control device Reference(s) Data source
2.	PROFILE	Profile number SAROAD Weight percent Peak ID
3.	SPECIES	SAROAD code CAS number Molecular weight
4.	SCC	SCC Profile number Quality indicator
5.	AREA SOURCE	Area source code Profile number Quality indicator

APPENDIX G

VOC SPECIATION TEST PROGRAM

APPENDIX G
VOC SPECIATION TEST PROGRAM

This appendix describes the VOC speciation testing efforts conducted as part of the overall speciation program to develop original speciated data to characterize high priority emission sources.

G.1 SUMMARY

Source categories where the VOC impacts are the most significant were selected for sampling: gasoline marketed, degreasing, drycleaning, autobody repair, and graphic arts. Due to resource limitations, emphasis was placed on area type emission sources which would not require ambient or stack sampling. The selection of specific sites for sampling within each category simply consisted of identifying major users/producers for each category. Samples were collected in a number of ways. Some of the samples were obtained from the producers through mail. In some cases, they were purchased from retail outlets. In other cases, they were obtained directly from the users.

Sample preparation involved development of proportions for making composite samples representative of a given category, from individual samples collected from each category. This was based primarily on data gathered through literature search, review of vendor literature, and vendor and trade association contacts. Composite samples from each category were analyzed using two analytical procedures. These procedures were similar to SW-846 Method 3810 "Headspace Method" and SW-846 Method 8270 "Gas Chromatography/Mass Spectrometry for Semi-Volatile Organics." All analytical determinations were performed using a combination of capillary gas chromatography with quadrupole mass spectrometry.

Accurate quantitative determinations were made for compounds included in the calibrations. In addition to these compounds, complete qualitative analysis was performed for all samples using a computerized library search

and a skilled interpreter of mass spectral data. In order to determine the relative weight percentages of compounds in a given sample, the values calculated accurately were integrated with the semi-quantitative values based on the qualitative analysis described above. The total organic content of the samples were then summed and each component was expressed as a percentage of the whole, consistent with the current VOC species profile format. A threshold level of 0.01 percent was used to include a compound in a profile.

The following sections discuss source category and site selection, sampling and analytical procedures, results, and internal quality assurance/quality control procedures in detail.

G.2 SELECTION OF SOURCE CATEGORIES AND SAMPLING SITES

G.2.1 Source Category Selection

To determine the source categories where the new and/or improved profiles would have significant impacts, the following were reviewed:[1,2]

- 1980 VOC Species Data Manual,
- 1980 National and Precipitation Assessment Program (NAPAP) Emissions Inventory, and
- New profiles developed from literature review.

Based on this review, the following source categories were selected for this sampling program:

- gasoline marketed,
- degreasing,
- drycleaning,
- autobody repair, and
- graphic arts-printing.

Table G-1 presents the Source Classification Codes (SCC's) and the applicable National Emissions Data System (NEDS) area source codes for these source categories. As shown in Table G-1, sampling in these categories would result in speciation of approximately 2,232,000 tons/year of VOC emissions; this is equivalent to about 10 percent of total national VOC emissions.[3] Due to time and budget limitations, emphasis was placed on area type emission sources which would not require ambient or stack sampling.

G.2.2 Selection of Sampling Sites

To characterize the five source categories selected for sampling, samples from major users/producers in each category were collected and the composition of potential VOC emissions associated with these products were characterized by laboratory methods. It was assumed that composition of the volatile portion of a product reflects the composition of VOC emissions from operations where the product is used.

Sample acquisition involved clearly defining each of the five source categories in terms of the products (i.e., types of solvents) used. Available literature was consulted to determine the major users/producers and their market share within the five categories. The major producers were solicited for representative samples. An alternate approach for certain categories was to purchase some of the products at local retailers once the products of interest have been specified.

In order to select sites for the gasoline marketed source category, the leading five oil companies in 1984 sales were identified from the "Basic Petroleum Data Book."[4] The five oil companies and corresponding local service stations where samples were collected included the following:

1. Chevron (Gulf)
2. Standard of Indiana (Amoco)
3. Texaco
4. Shell
5. Exxon

TABLE G-1. SOURCE CATEGORIES SELECTED FOR SAMPLING[a]

SCC/Area Source Code	Description	National VOC Emissions (tons/yr)	% of National VOC Emissions
54	Gasoline marketed	966,000	4.2
78,4-01-002	Degreasing	607,000	2.6
79	Drycleaning	300,000	1.3
83	Autobody repair	183,000	0.8
80	Graphic arts-printing	176,000	0.8
		2,232,000	9.7

[a]Source: Reference 3.

The 1984 sales data presented for Chevron Corporation reflected the acquisition of Gulf Corporation. No local Chevron stations could be found, so only Gulf service stations were selected for collecting samples.

Degreasing and drycleaning operations use similar solvents and the producers of solvents used in these operations are often the same for each industry. The main type of solvent used in both industries that is not a pure compound is mineral spirits. Since evaporative emissions from a pure solvent can be accurately assumed to be the compound comprising the solvent, mineral spirits was the only solvent type which was investigated in this study. Major producers of mineral spirits were identified through contacts with trade associations and vendor literature review. As a result of these contacts, one company provided a sample of their main mineral spirit product and another company sent five of their mineral spirit products through the mail in 4-ounce sample bottles with minimal headspace.

The main producers of automotive aftermarket paint (i.e., paint applied after the car leaves the factory) were identified by review of vendor literature and by talking with sales representatives. The main types of paint used presently within the industry were identified along with their tradenames for each main producer. Once the tradenames of the samples were established, local paint distributors were contacted to see if they carried the product, along with the compatible thinner. Paint distributors of DuPont, Sherwin-Williams, and PPG (Ditzler) paints were selected. The types of paints and thinners selected are as follows:

- DuPont - "Centari," and "Lucite"
- Sherwin-Williams - "Acrylyd," "Kem Transport," and Acrylic Enamel
- PPG (Ditzler) - "Ditzco"

For the graphic arts industry, the main industry subcategories identified from Reference 5 were:

1. Rotogravure
2. Lithography
3. Letter Press
4. Flexography

The main types of printed products (i.e., newspaper, magazine, etc.) made with each of these printing processes were identified from the Printing Ink Handbook.[6] Local printers which use these processes were contacted and samples were obtained by mail or arrangements were made to pick up the ink samples.

G.3 SAMPLING AND ANALYTICAL PROCEDURES

G.3.1 Sampling Procedures

Table G-2 presents an overview of the sample collection efforts including information on the number and type of samples collected, the number of participating companies, and how the samples were actually obtained.

When samples were obtained on a first hand basis by visiting sites, an attempt was made to minimize VOC loss. The time the sample was exposed to the open air was reduced as much as possible. Before taking gasoline samples, approximately one gallon of gasoline was dispensed to purge the delivery hose. This gasoline was not desirable because it was exposed to ambient summer temperatures and may have lost the more volatile components. Gasoline samples were collected in clean vials obtained from the Radian laboratory. As soon as each gasoline sample was sealed and labeled, it was placed in a plastic bag and put in an ice chest. The samples were then transported to the $4^{o}C$ walk-in freezer at the Radian laboratory.

One sample for the degreasing and drycleaning categories was obtained directly from the producer. It was stored along with five other solvents received by mail in the walk-in freezer.

Acquisition of autobody repair paint was a simple matter of purchasing the desired paint and its compatible/recommended thinner at local paint distributors. The paint which was in metal cans or plastic bottles, was then transported to the walk-in freezer.

Most of the printing inks for the graphic arts category were obtained by site visits. One lithographic ink sample was obtained by mail and taken to the walk-in freezer. Letterpress, flexographic, and gravure ink samples

TABLE G-2. VOC SAMPLE COLLECTION

Source Category	Sample Acquisition	Number of Samples	Number of Participating Companies	Types of Samples	Date
Gasoline Marketed	Site Visit	14	5	Leaded, Unleaded, and Unleaded Premium Gasoline	7/14/87
Degreasing	Mail, Site Visit	6	2	Mineral Spirits	7/16/87, 7/17/87
Drycleaning	Mail, Site Visit	5	2	Mineral Spirits	7/16/87, 7/17/87
Autobody Repair	Site Visit	12	3	Acrylic Enamel, Acrylic Lacquer, and Alkyd Enamel Paints and Thinners	7/17/87
Graphic Arts	Site Visit, Mail	5	4	Flexographic, Lithographic, Gravure, and Letterpress Printing Inks	7/16/87

were obtained by drawing off ink samples from the actual printing processes. An attempt was made to minimize the headspace in the sample, but this could not be monitored carefully because only authorized personnel were allowed near the moving machinery to extract the sample. In any case, the headspace was small. Since inks typically contain compounds with high boiling points (i.e., low volatility), this would have a negligible impact on the results. The samples were sealed, labeled and stored in an ice chest until taken to the laboratory.

G.3.2 Compositing Procedures

After all the samples for a given source category were collected, a composite sample for each source category was developed in the laboratory. The actual number of samples used to develop the composite sample varied between categories. At least five samples from each category were included in each composite.

Composite samples were developed according to the type of data available for a given category. If product usage data were available, then the individual samples were mixed in proportion to the usage data. For example, if 2,000 tons/year of solvent X and 1,000 tons/year of solvent Y were used in a source category, then the composite sample consisted of solvent X and solvent Y combined in a two-to-one ratio. If emissions data were available for a source category, then the composite sample was developed in proportion to the emissions data. If usage or emissions data were insufficient, the individual samples for a particular category were combined in equivalent proportions.

The specific compositing procedure used for each category is described in detail below. In each case, the composite was prepared in a walk-in refrigerator at $4^{o}C$ immediately prior to analysis.

G.3.2.1 Gasoline Marketed Composite. In developing the composite for this category, 1984 sales data for the leading five oil companies was used to determine the percent contribution to U.S. sales.[4] Thirty-eight percent of the U.S. gasoline market is characterized by this composite sample.

Breakdown of company sales figures by gasoline type (i.e., leaded, unleaded, etc.) was based on average data for 1985 and 1986.[7] Amoco no longer carries leaded gasoline, so the percent contribution to Amoco sales was based only on unleaded regular and unleaded premium gasoline.

The assumptions used to develop this composite included the following: (1) the company contributions to the market are based on 1984 sales data; (2) sample based on Chevron and Gulf sales is represented only by Gulf gasoline; (3) average of 1985 and 1986 nationwide production data was used to estimate the percentage of gasoline types per company; (4) gasoline was only sampled in the Research Triangle area (North Carolina); (5) since samples were collected in July, this composite does not reflect winter-blend gasolines.

The proportions in Table G-3 were used to make up 100 mL of the composite. Of this volume, 30 mL (22.6 g) was put into a 40 mL septum-top VOA vial and put into a freezer until analysis.

G.3.2.2 Degreasing Composite. Data of sufficient quality were not available which could be used to composite the mineral spirit samples. All six mineral spirit samples were composited by volume in equal amounts as shown in Table G-3. The final volume of the degreasing composite was 120 mL. Of this volume, 30 mL (23.1 g) was measured into a 40 mL septum capped VOA vial and stored in a freezer until analysis.

G.3.2.3 Drycleaning Composite. Five of the six mineral spirit samples were composited by volume in equal proportions since no data were available to permit compositing by varying amounts (see Table G-3). The sixth sample was not included because of its high volatility. Most mineral spirits used by small independent dry cleaners have a minimum flash point of around $100^{o}F$. The sixth sample had a flash point of less than $20^{o}F$, which was not typical of petroleum drycleaning solvents and, therefore, was not included in the analysis.

The final volume of the drycleaning composite was 100 mL. Of this volume, 30 mL (23.3 g) was measured into a septum capped 40 mL VOA vial and stored in a freezer until analysis. A duplicate sample was prepared by

measuring a second 30 mL volume of the composite (22.8 g) into a 40 mL septum capped VOA vial. The duplicate sample was also stored in a freezer until analysis.

G.3.2.4 Autobody Repair Composite. The composite for this category was developed using a method similar to the one used for the gasoline marketed category. A list of main automotive aftermarket paint producers with their percent contribution in sales to the market was used to develop the autobody repair composite (see Reference 8). This information was coupled with information on main autobody paint types and their percent contribution to the company-wide paint sales for each company to develop the criteria for compositing. By obtaining two samples of DuPont paint, three samples of Sherwin-Williams paint, and one sample of Ditzler paint, 42 percent of the market was characterized. The following assumptions were made in the development of the composite: (1) paints all cost roughly the same to remain competitive in the market, thus sales percentages were assumed to be the same as production percentages; and (2) each company had the same percent contribution to sales for each type of paint.

Paints were combined with the thinners/reducers according to the instructions provided on the paint cans resulting in actual paint samples. Approximately 1:1.25 to 1:1.5 proportions of paint and thinner were used for each sample. Each paint sample of a certain type and company origin was then combined according to the scheme presented in Table G-3. The total volume of this composite was 100 mL, of which 30 mL (27.3 g) was measured into a 40 mL VOA vial and stored in a freezer until analysis.

Samples of polyurethane and acrylic urethane paints were not considered because of the potential problems with mixing these paints into the composite. Paints of this type require an activator to make the paint harden. This possibly could form lumps of reacted paint in the composite. In addition, the reactivity of all components with other paint mixtures was unknown.

G.3.2.5 Graphic Arts Composite. Compositing of graphic arts inks was based on 1978 nationwide mass emissions.[5] Since the composite was based on mass emissions, the individual ink samples were composited by weight percent

according to the proportions shown in Table G-3. Two gravure samples were mixed in equal amounts to obtain one gravure sample. For this category, only one company was sampled per each subcategory (flexography, gravure, letterpress, and lithography).

The total composite amount was 101.0 g. Of this amount, 21.1 g was put into a 40 mL septum capped VOA vial and stored in a freezer until analysis.

G.3.3 Analytical Procedures

G.3.3.1 Headspace Analysis. All of the composite samples were subjected to analysis of the headspace of the VOA vials. The headspace of the gasoline sample was sampled at room temperature. All of the other composites were allowed to equilibrate in an oven at 90°C for one hour before the headspace was removed for analysis.

The combination of capillary gas chromatography (DB-5 fused silica capillary column, 30 m, 0.32 mm ID, 1.0 microns film thickness) with quadrupole mass spectrometry was used to perform all analytical determinations. For the headspace analyses, a coil of the column was frozen with liquid nitrogen to allow the introduction of the gaseous materials from the VOA vial headspace by a direct injection using a gas-tight syringe. The optimum sample size was determined as 1 ul. The temperature program used consisted of an initial temperature of -50°C for 1 minute and an increase of 6°C per minute up to a final temperature of 250°C. The analytical system was tuned using perfluorotributylamine (FC-43), according to the manufacturer's specifications. An accurate three-point calibration was performed using the Air Toxics quantitation standards and surrogates (see Table G-4).

The calibration samples were prepared as a mixture of compounds in a static dilution bulb from which gaseous injections were made to calibrate the analytical system.

G.3.3.2 Semi-Volatile Analysis. A weighed quantity of the composite was put into a carbon disulfide solution and an analysis of the organic contents of the carbon disulfide solution was performed using GC/MS in order

TABLE G-4. CALIBRATION COMPOUNDS FOR HEADSPACE ANALYSIS

Trichlorofluoromethane	Tetrachloroethene
1,1-Dichloroethene	Dibromochloromethane
Methylene chloride	Chlorobenzene
trans-1,2-Dichloroethene	Ethylbenzene
1,1-Dichloroethane	m-, p-Xylene
Chloroform	o-Xylene
1,1,1-Trichloroethane	Bromoform
Carbon tetrachloride	1,1,2,2-Tetrachloroethane
Benzene	m-Dichlorobenzene
1,2-Dichloroethane	p-Dichlorobenzene
Trichloroethene	o-Dichlorobenzene
1,2-Dichloropropane	Styrene
Bromodichloromethane	Acetone
trans-1,3-Dichloropropene	2-Butanone
Toluene	Heptane
cis-1,3-Dichloropropene	Isopropylbenzene
1,1,2-Trichloroethane	Hexane
Chloromethane	Vinyl chloride
Bromomethane	Chloroethane

to assess whether compounds were detected under these conditions when those same compounds could not be observed in the headspace analysis. Since carbon disulfide is not a polar compound, it was judged to be an optimal agent for dissolving any polar or nonpolar compounds that may exist in a sample. The system was calibrated for the target compounds of SW-846 Method 8270. A three-point calibration was performed for the compounds listed in Table G-5. The sample size used for this analysis was also 1 uL. The temperature program used consisted of an initial temperature of 35^{o}C for 4 minutes and an increase of 10^{o}C per minute up to 270^{o}C.

G.4 RESULTS AND DISCUSSION

G.4.1 Headspace Analyses

The technique used for analysis of headspace from composite samples equilibrated at 90^{o}C for 1 hour was similar to SW-846 Method 3810 "Headspace Method." In this study, the method was intended for identification and quantification of volatile organic compounds with boiling points less than ~100^{o}C.

For analysis of headspace samples, an accurate three-point calibration was performed for compounds that are designated as Air Toxics Standards (see Table G-4). In addition to accurate quantitative determination of these compounds, a complete qualitative analysis was performed on all samples using the combination of computerized library search techniques and a skilled interpreter of mass spectral data. Compounds were identified and semi-quantitative values were calculated using a response factor of one relative to the analytical standard. By far the major components of most samples were hydrocarbons; alkanes, alkenes, and aromatic compounds. In most cases, a definitive identification of specific isomers could not be made, so a class identification was made (e.g., methyl pentane).

In order to determine the relative percentages of the organic compounds, the values which are calculated accurately for compounds included in the calibration curve were integrated with the values calculated on the basis of a relative response factor of one. The total organic content of

TABLE G-5. CALIBRATION COMPOUNDS FOR SEMI-VOLATILE ANALYSIS

Benzyl alcohol	Bis(2-chloroethyl)ether
Bis(2-chloroisopropyl)ether	2-Chlorophenol
1,3-Dichlorobenzene	1,4-Dichlorobenzene
1,2-Dichlorobenzene	Ethyl methane sulfonate
Hexachloroethane	Methyl methane sulfonate
2-Methylphenol	4-Methylphenol
N-nitrosodimethylamine	N-nitroso-di-n-propylamine
Phenol	2-Picoline
Aniline	Acetophenone
Benzoic acid	Bis(2-chloroethoxy)methane
4-Chloroaniline	4-Chloro-3-methylphenol
2,4-Dichlorophenol	2,6-Dichlorophenol
2,4-Dimethylphenol	Hexachlorobutadiene
Isophorone	2-Methylnaphthalene
Naphthalene	Nitrobenzene
2-Nitrophenol	N-nitroso-di-n-butylamine
N-nitrosopiperidine	1,2,4-Trichlorobenzene
Acenaphthene	Acenaphthylene
1-Chloronaphthalene	2-Chloronaphthalene
4-Chlorophenyl phenyl ether	Dibenzofuran
Diethyl phthalate	2,6-Dinitrotoluene
Fluorene	Hexachlorocyclopentadiene
1-Naphthylamine	2-Naphthylamine
2-Nitroaniline	3-Nitroaniline

TABLE G-5. CALIBRATION COMPOUNDS FOR SEMI-VOLATILE ANALYSIS (Continued)

4-Nitroaniline	4-Nitrophenol
Pentachlorobenzene	1,2,4,5-Tetrachlorobenzene
2,3,4,6-Tetrachlorophenol	2,4,6-Trichlorophenol
2,4,5-Trichlorophenol	4-Aminobiphenyl
Anthracene	4-Bromophenyl phenyl ether
di-n-Butyl phthalate	4,6-Dinitro-2-methylphenol
Diphenylamine	1,2-Diphenylhydrazine
Fluoranthene	Hexachlorobenzene
N-nitrosodiphenylamine	Pentachlorophenol
Pentachloronitrobenzene	Phenacetin
Phenanthrene	Pronamide
Benzidine	Benzo(a)anthracene
Bis(2-ethylhexyl)phthalate	Butyl benzyl phthalate
Chrysene	3,3-Dichlorobenzidine
p-Dimethylaminoazobenzene	Pyrene
Benzo(b)fluoranthene	Benzo(k)fluoranthene
Benzo(g,h,i)perylene	Benzo(a)pyrene
Dibenz(a,h)anthracene	7,12-Dimethylbenz(a)anthracene
di-n-Octyl phthalate	

the sample was then summed and the quantity of each component was expressed as a percentage of the whole to be consistent with the current VOC species profile format. A threshold level of 0.01 percent was used to include a compound in a given profile. See example calculations below for a hypothetical composite sample.

Assume for composite sample A, the following compounds were identified and quantified:

Species	ng	Relative % = (ng/total ng) 100
Benzene*	80	12.82
Toluene*	100	16.03
o-Xylene*	25	4.01
Isopropylbenzene**	62	9.94
Hexane**	50	8.01
Cyclohexane**	300	48.08
Methylundecane**	7	1.12
TOTAL ng	624	100.01

*Compounds that are accurately quantified (i.e., compounds included in the three-point calibration).

**Compounds that are identified using computerized library search and a skilled interpreter of mass spectral data (i.e., compounds not included in calibration).

G.4.2 Semi-Volatile Analyses

Identification and quantification of semi-volatile organic compounds (boiling points greater than 100°C) was made using procedures similar to SW-846 Method 8270 "Gas Chromatography/Mass Spectrometry for Semi-Volatile Organics." This method is very similar to Method 625 proposed in the Test/Quality Assurance Project Plan. For example, the set of target compounds used in both methods is the same. Differences between the two methods are believed to be relatively unimportant as they relate to the overall program objectives. In analysis of semi-volatile compounds, an accurate three-point calibration was performed for target compounds of Method 8270 (see Table G-5).

As discussed in Section G.4.1 for headspace analyses, accurate quantitative determination of the target compounds was performed. This was combined with the qualitative analysis performed on all samples using a computerized library search and a skilled interpreter of mass spectral data. The compounds identified in this manner were quantified using a response factor of one relative to the analytical standard. Similar to the results observed from headspace analyses, the major components of most samples were hydrocarbons; alkanes, alkenes, and aromatics. Since a definitive identification of specific isomers was not possible in most cases, a class identification was made.

The calculations used for developing the VOC profiles from the analytical data are the same as those discussed in Section G.4.1 for the headspace method.

G.4.3 Discussion of Results

G.4.3.1 Gasoline Marketed, Degreasing, and Drycleaning Categories. At the onset of the program, it was anticipated that there would be two relatively distinct ranges of compounds (according to their boiling points or molecular weights). These ranges would be characterized by the two analytical methods. Some overlap was also expected. Comparison of data, based on headspace and semi-volatile analyses, for some composite samples, however, showed a different trend. For the gasoline marketed, degreasing, and drycleaning composite samples, the species identified using the two methods fall approximately in the same range (according to molecular weight). For example, headspace analytical results for the degreasing composite span a range from C_6 through C_{14}. The semi-volatile analysis for the same composite covers a similar range from C_6 through C_{12}. The respective ranges for the headspace and semi-volatile analyses for the gasoline marketed composite were C_4 through C_{12} and C_6 through C_{12}. For the drycleaning composite, these ranges were C_7 through C_{13} and C_6 through C_{16}. In the latter case, the identification of a very small quantity of di-n-butyl phthalate (C_{16}) in the sample was attributed to possible contamination prior to sample collection. If contamination did occur, the

range covered by the semi-volatile analysis for the drycleaning composite would be C_6 to C_{12}, which is in agreement with the ranges observed for the other two composites discussed above.

Although there is good agreement in the ranges of compounds identified and quantitated for the gasoline marketed, degreasing, and drycleaning composites, it is difficult to compare the percentages for a given compound from the two analyses for these categories. In some cases, a compound was reported in one analysis and not reported in the other analysis. The judgement call made by the computer and/or the analyst during analysis of the data (i.e., where peaks do not resolve completely, where there is enough of a valley to decide that another peak is occurring, etc.) was probably one of the reasons why a compound is observed in one analysis and not in the other.

In other cases, the values for the same compound were significantly different. One of the reasons contributing to this discrepancy is probably the use of semi-quantitative values based on a relative response factor of 1 in the VOC species profiles. In some cases, this may have resulted in a significant bias in the relative percentages. Due to resource limitations, it was not possible to fine tune the analytical procedures. It is believed that some effort on method development would be necessary in order to get better agreement between the two methods.

G.4.3.2 Autobody Repair and Graphic Arts Categories. For the autobody repair and graphic arts composites, a wider range of species was observed with the semi-volatile analysis. For the autobody repair composite sample, the ranges spanned using the headspace and semi-volatile analyses were C_3 through C_{11} and C_6 through C_{19}, respectively. The corresponding ranges for the graphic arts composite sample were C_3 through C_{12} and C_6 through C_{21}. In contrast with the ranges observed for the gasoline marketed, degreasing, and drycleaning composites, the semi-volatile analysis results for autobody repair and graphic arts samples covered a wider range. Several compounds that were not found in the headspace analysis were identified including significant quantities of phthalates.

G.4.3.3 VOC Species Profiles. The headspace analytical results were considered representative of the gasoline marketed, degreasing, and drycleaning composite samples. The semi-volatile analytical results were considered representative of the autobody repair and graphic arts composite samples due to the wider range of compounds identified. Generally speaking, the headspace method simulates real-life situations more closely than the method used in identifying and quantifying semi-volatile compounds. In the latter method, the species in a given sample are forced into a solution (using carbon disulfide in this case). The solution is then analyzed. Solubility of the species in a given sample determines the extent to which the species can be identified and/or quantitated.

The profiles developed in this study include the following:

Profile Number	Profile Name
1190	Gasoline Marketed
1191	Graphic Arts-Printing
1192	Degreasing
1193	Drycleaning
1194	Autobody Repair

G.5 INTERNAL QUALITY ASSURANCE/QUALITY CONTROL

G.5.1 Sampling Quality Control

Sampling quality control activities focused on ensuring the cleanliness of the sampling equipment and the proper logging and documentation of each sample to avoid loss of sample integrity. The time each sample was exposed to the open air was reduced as much as possible.

Gasoline samples were collected in vials precleaned by Radian personnel. Before collecting a gasoline sample, approximately one gallon of gasoline was dispensed to purge the delivery hose of ambient temperature gas which may have lost the more volatile compounds due to high summer temperatures. Letterpress, flexographic, and gravure ink samples were obtained by drawing off ink samples from the actual printing processes. The

headspace in the sample vial was minimized as much as possible. The remaining samples (degreasing, drycleaning, autobody repair, and lithographic ink) were all purchased or obtained directly in sealed containers.

Sample compositing procedures were based on proportions developed for each source category as discussed in Section G.3.2. A minimum of five samples from each category was included in each composite.

G.5.2 Analytical Quality Control

The analyses for this program were performed using accepted laboratory procedures in accordance with the specified analytical protocols. The following general QC procedures were incorporated into the analytical effort, where applicable:

- The Analytical Task Leader reviewed all analytical data and QC data on a daily basis for completeness and data quality.
- A master logbook was maintained to record all pertinent sample information.
- All hardcopy raw data (i.e., chromatograms, computer printouts, etc.) were maintained in organized files.

The following sections summarize the results of all analytical QC data. This includes surrogate recoveries, duplicate analyses, control samples, and blank samples.

G.5.2.1 Surrogate Compounds. Each sample analyzed was spiked with surrogate compounds prior to analysis. The use of surrogates is essential to monitor the efficiency of the analytical process. The compounds were spiked into the matrix prior to initiation of any sample preparation procedures (following sample compositing) and carried through the entire analytical process. The QC criteria is surrogate recovery within $\pm$50 percent. The surrogate results are presented in Tables G-6 and G-7. As

TABLE G-6. SURROGATE RECOVERIES OF VOC SAMPLES - HEADSPACE ANALYSES

Sample	Surrogates[a,b]		
	Perfluorobenzene	Perfluorotoluene	D_{10}-Ethylbenzene
Autobody Repair	91	79	74
Drycleaning Composite	90	87	84
Drycleaning Composite (Duplicate)	90	88	87
Degreasing Composite	79	76	84
Graphic Arts Composite	90	86	97
Gasoline Composite	100	98	92

[a]All values reported as percent surrogate recovery.

[b]The QC criterion was surrogate recoveries within ±50 percent.

TABLE G-7. SURROGATE RECOVERIES OF VOC SAMPLES - CARBON DISULFIDE (SEMI-VOLATILES) ANALYSES

Sample	Surrogates[a,b]					
	2-Fluorophenol	D_6-Phenol	D_5-Nitrobenzene	2-Fluorobiphenyl	2,4,6-Tribromophenol	D_{14}-Terphenyl
Graphic Arts Composite	98	94	100	101	89	110
Drycleaning Composite	94	79	77	99	89	104
Drycleaning Composite (Duplicate)	90	79	75	97	97	97
Degreasing Composite	95	78	77	97	93	100
Autobody Repair Composite	87	83	76	96	102	96
Gasoline Composite	90	82	75	95	101	96
Method Blank	107	95	105	105	91	122
QC Sample	102	95	101	104	95	113

[a] All values reported as percent surrogate recovery.

[b] The QC criterion was surrogate recoveries within ±50 percent.

seen from the tables, all surrogate recoveries were well within the QC criteria, averaging 87 percent for the headspace samples and 94 percent for the carbon disulfide solutions (semi-volatiles).

G.5.2.2 Method Blank. One method blank sample was processed and analyzed for the sample set to assess the background levels present in the analytical system. The method blank was a reagent sample (carbon disulfide) taken through the entire sample preparation and analytical process. It was spiked with the same surrogate compounds and quantitation standards as the field samples so that recoveries could be calculated. (The field sample results were not corrected for the concentrations of compounds found in the method blank.)

The compounds and their respective concentrations found in the method blank were as follows:

Benzene	62.0 ng/uL
Cyclohexane	62.0 ng/uL
$C_{16}H_{30}O_4$	10.6 ng/uL
Cyclohexene	6.4 ng/uL
Methylene chloride	4.2 ng/uL
Unknown	1.7 ng/uL
N-phenylaniline	1.5 ng/uL

The only compounds present in significant quantities were benzene and cyclohexane. Benzene is a common contaminant found in carbon disulfide and it is virtually impossible to find carbon disulfide which is benzene free. Cyclohexane is frequently added to organic solvents as a stabilizer and cyclohexene is often added to organic solvents as an anti-oxidant. $C_{16}H_{30}O_4$ and N-phenylaniline were both observed in all of the samples analyzed and are both considered to be chromatographic artifacts from the column. The unknown is a small quantity of compound that is an artifact of the column or solvent, which could not be identified. It was not observed in the samples and is considered to be insignificant in terms of quantity.

G.5.2.3 Duplicate Analyses. The composite sample from the dry cleaning category was analyzed in duplicate for both headspace and semi-volatile compounds. The duplicate sample was analyzed in order to evaluate the reproducibility of the analytical methodology for the headspace and semi-volatiles analyses. The QC criteria for agreement of the two results for the same compound, in terms of total micrograms, were within ±50 percent for each VOC detected.

In the case of the duplicate drycleaning headspace sample, the compounds identified were the same, but the signal levels for the compounds in the two samples differed by approximately 50 percent. This roughly 50 percent difference was observed for the two results, expressed in total micrograms. The two samples used to determine results #1 and #2 were taken from the same composite, at approximately the same volume (22.8 grams in one case, 23.3 grams in the other). The same volume of the headspace was injected after the vials containing the sample had been heated to 90°C. Scan times are exactly the same for the same compounds. There is no explanation for the difference in the headspace samples. The only possible explanation is that, for some reason, substantially less material was delivered to the ion source in one case than in the other. Since the quantitation standards were introduced separately from a static dilution bulb, it is possible for the standards to be consistent while the values obtained for the samples differ. The close correspondence of the standards shows that there was nothing inherently irreproducible in the analytical process. The better comparison is the relative percentages (weight percents) of any two compounds which appear to be more reproducible than the absolute values (micrograms). Since the relative percentages are the data that will be used in the VOC species profiles, this is an appropriate comparison.

The two results for the semi-volatiles duplicate analysis are all within the QC criteria of ±50 percent agreement between results #1 and #2 for the same compound. However, several compounds were identified in the second analysis in quantities which were nondetectable in the first analysis. This is not unusual since the presence of a given compound is decided upon by the computer and/or analyst who must decide what constitutes a peak. This type of judgement may explain why in some instances a compound is observed in one analysis and not in the other.

16. ABSTRACT

The U.S. Environmental Protection Agency (EPA) has several ongoing activities that require speciated volatile organic compounds (VOC) or particulate matter (PM) profiles from several source categories. In 1980, EPA published the "Volatile Organic Compound (VOC) Species Data Manual, Second Edition," EPA-450/4-80-015, which provided VOC species profiles for some emission source categories. More recently, EPA published the "Receptor Model Source Composition Library," EPA-450/4-85-002, which contains PM species profiles for several source categories. As part of an effort to update the VOC and PM profile data bases, EPA has initiated several studies. The objective of the current study was to evaluate, revise, and update 1) the 1980 VOC Data Manual, and 2) the Source Composition Library.

The updated VOC species profile data base is contained in Volume I of this document. The VOC profile data base includes VOC profiles from primarily three sources: 1) the 1980 VOC Data Manual, 2) new VOC profiles developed from readily available existing data, and 3) new VOC profiles developed from original data as a result of the VOC speciation field sampling program. In addition to the VOC profiles, Volume I contains profile assignments that link a profile to a source category. For categories where profile data are not available, the profile assignments are based on engineering judgment.
